

HICKEY

☐ **SCIENCE Quarterly:**

It appears that mosquitos can be cured of infecting us with malaria by making them eat cheese fungus. After they've eaten blood, they have a rest because they are too tired to fly. If you smear where they sit with cheese fungus, it gets into the mosquito, they become even slower and eventually grind to a halt. I am told by the boffins at Edinburgh University that this is a "green" method of murdering mosquitos and precludes the use of insecticides. However, it must make one's house a bit smelly so I'll continue to employ vast doses of banned DDT (with which I clean the staff quarters).
